Three coffees a day linked to a range of health benefits

Research based on 200 previous studies worldwide says frequent drinkers less likely to get diabetes, heart disease, dementia and some cancers

Heard on Morning Edition

There's a growing body of evidence suggesting that compounds found in cocoa beans, called polyphenols, may help protect against heart disease.

Study: [Kwok et al. \(2015\)](#)

Observation

- **Individuals, study subjects, participants, units**
 - European adults
- **Treatment**
 - chocolate consumption
- **Outcome**
 - heart disease

The First Question

Is there any relation between chocolate consumption and heart disease?

- Association
 - Any relation
 - Link

Some data:

"Among those in the top tier of chocolate consumption, 12 percent developed or died of cardiovascular disease during the study, compared to 17.4 percent of those who didn't eat chocolate."

[Howard LeWine of the Harvard Health Blog](#)

→ This suggests there may be an association

The next question

Does chocolate consumption lead to a reduction in heart disease?

- Causality
→ This question is often harder to answer.

"[The study] doesn't prove a cause-and-effect relationship between chocolate and reduced risk of heart disease and stroke."

→ it is an *observational study*

JoAnn Manson, chief of the Division of Preventive Medicine at Brigham and Women's Hospital in Boston

Association

London, early 1850's

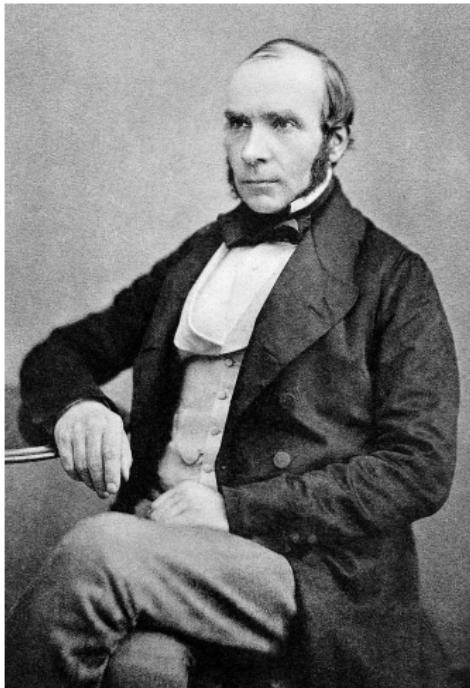

- Cholera reached London in early 1930s
- It was greatly feared in 19th century London as it was often deadly
- Referred to as “King Cholera” in London
- An outbreak in 1849 killed over 14,000 people in London
- Foul-smelling neighborhoods

Illustration by John Leech from Punch (1852).

Miasmas, miasmatism, miasmatists

- Bad smells given off by waste and rotting matter
- Believed to be the main source of disease
- Suggested remedies:
 - “fly to clene air”
 - “a pocket full o’ posies”
 - “fire off barrels of gunpowder”
- Staunch believers:
 - Florence Nightingale
 - Edwin Chadwick, Commissioner of the General Board of Health

John Snow, 1813-1858

John Snow

- Anesthesiologist in London
- Did not believe the miasmas theory
- From examining symptoms, suspected food/drink
- Final suspect: dirty water
- Pioneer of modern epidemiology

The map displays the area around John Snow pub, located at 39 Broadwick St, Soho, London W1F 9QJ, UK. The pub is marked with a red pin and a small info box. The surrounding area includes Regent St, New Burlington St, and Golden Square. Other nearby establishments shown include The London Palladium, Aqua Spirit, Ping Pong Soho, Reckless Records, Milk & Honey, Cirque le Soir, Red Lion, Old Coffee House, Flat Iron, Bob Bob Ricard, Anthropologie, Nopi, Bill's Soho, Arang, The Glasshouse Stores, and The White Smith's. The map also shows the locations of various coffee shops, restaurants, and bars like Bucks Coffee, Sketch, H&M Oxford Circus, COS Liberty London, and The Photographers' Gallery. Landmarks such as the Courthouse and the Palace Skateboards are also visible.

Causation

London Water Supply

Lambeth drew water upriver from sewage dump into the River Thames
Southwark & Vauxhall drew from below the sewage dump
Snow focused on intersection ("Both")

Method of Comparison

- **Treatment group**
- **Control group**
→ does not receive the treatment

Compare the outcomes of these two groups
If the results differ, it could suggest an association

Snow's "Grand Experiment"

"... there is no difference whatever in the houses or the people receiving the supply of the two Water Companies, or in any of the physical conditions with which they are surrounded ..."

- The two groups were similar *except for the treatment.*

Snow's table

	Number of houses.	Deaths from Cholera.	Deaths in each 10,000 houses.
Southwark and Vauxhall Company	40,046	1,263	315
Lambeth Company	26,107	98	37
Rest of London	256,423	1,422	59

Image credit: <https://www.vauxhallandkennington.org.uk/cholera.shtml>

Key to establishing causality

If the treatment and control groups *are similar apart from the treatment*, then differences between the outcomes in the two groups can be ascribed to the treatment.

Confounding

Trouble

If the treatment and control groups have **systematic differences other than the treatment**, then it might be difficult to identify causality.

Such differences are often present in **observational studies**.

When they lead researchers astray, they are called **confounding factors**.

Randomize!

- If you assign individuals to treatment and control **at random**, then the two groups are likely to be similar apart from the treatment.
- You can account – mathematically – for variability in the assignment.
- **Randomized Controlled Experiment**

Careful...

Regardless of what the dictionary says, in probability theory

Random \neq Haphazard
